

Product Overview

Aegis Nexus is an AI-enabled cloud infrastructure designed to address the growing mismatch between mobile game size and smartphone storage capacity. Modern mobile games frequently exceed tens of gigabytes in size, forcing users to delete existing apps or abandon new installations entirely. Aegis Nexus replaces the traditional full-download model with an AI-driven asset streaming system.

Target Customer, Value Proposition, and Revenue Model

The primary target customers are mobile gamers using mid-range smartphones with limited storage. These users often uninstall games due to large downloads or frequent updates but still expect high-quality gameplay.

Aegis Nexus enables players to access AAA-quality games without worrying about storage space. By separating gameplay logic from large asset files, the platform dramatically reduces installation size and allows players to start games almost instantly. For publishers, the platform lowers installation friction and improves user retention.

Simulated CLV Analysis

The analytical component of this project estimates Customer Lifetime Value (CLV) to guide acquisition spending and subscription strategy. Because the product has not yet launched, the analysis will rely on a simulated dataset of approximately 100,000 users representing potential behavior on a cloud gaming subscription platform. The dataset will include variables such as subscription tier, monthly retention probability, user activity level, customer acquisition cost (CAC), and estimated cloud infrastructure cost per user.

Using this dataset, the analysis will estimate average CLV and the variation of user value across segments. The results will identify the maximum sustainable CAC and the expected payback period for acquisition spending. Sensitivity analysis will examine how CLV changes under different churn rates, subscription adoption levels, and infrastructure costs. These insights will inform launch decisions such as marketing budget allocation and which subscription tier should be prioritized during early growth.

Go-to-Market Strategy and AI in Marketing

The platform will operate under a subscription model integrated with game publishers. Players pay a monthly fee to access the asset streaming service while publishers share revenue from participating titles. Two subscription tiers will be offered: a basic plan for standard gameplay and a premium plan that provides higher graphical fidelity and priority access to cloud resources.

Customer acquisition will rely primarily on digital marketing channels common in the mobile gaming ecosystem. Playable advertisements on social media platforms will allow users to experience a short, streamed demo directly within the ad before installing the client. AI tools will support marketing execution by generating advertising creatives and optimizing programmatic ad bidding, while human decision-makers guide positioning, pricing, and overall strategy.
